

Problem 4: Count the Vowels

Name: _____

Function to write: `countVowels(str)`

Write a function `countVowels(str)` that returns the number of vowels (a, e, i, o, u — lowercase only) in a string, using a for loop that checks each character one at a time.

- Loop through every index of the string
- Use an if statement to check whether that character is a vowel
- Access a character by index with `str[i]` or `str.charAt(i)`

This combines a loop with a conditional. You can check one character against several vowels using `||`:
`char === "a" || char === "e" || ...`

Test Cases — fill in the expected output before you run your code

#	Call	Expected Output
1	<code>countVowels("hello")</code>	
2	<code>countVowels("javascript")</code>	
3	<code>countVowels("xyz")</code>	
4	<code>countVowels("aeiou")</code>	

HINT

`str.length` gives you how many characters to loop through — your loop condition should stop before running out of characters.
